FMS6501 12 Input / 9 Output Video Switch Matrix with Input Clamp, Input Bias Circuitry, and Output Drivers

Features

- 12 x 9 Crosspoint Matrix
- Supports SD, PS, and HD 1080i/1080p Video
- Input Clamp / Bias Circuitry
- AC or DC-Coupled Inputs
- AC or DC-Coupled Outputs
- Dual-Load (75Ω) Output Drivers with High-Impedance Disable
- One-to-One or One-to-Many Input to Output Switching
- Programmable Gain: +6, +7, +8, or +9dB
- I²CTM Compatible Digital Interface, Standard Mode
- 3.3V or 5V Single-Supply Operation
- Lead-Free SSOP-28 Package

Applications

- Cable and Satellite Set-Top Boxes
- TV and HDTV Sets
- A/V Switchers
- Personal Video Recorders (PVR)
- Security / Surveillance
- Video Distribution
- Automotive (In-Cabin Entertainment)

Description

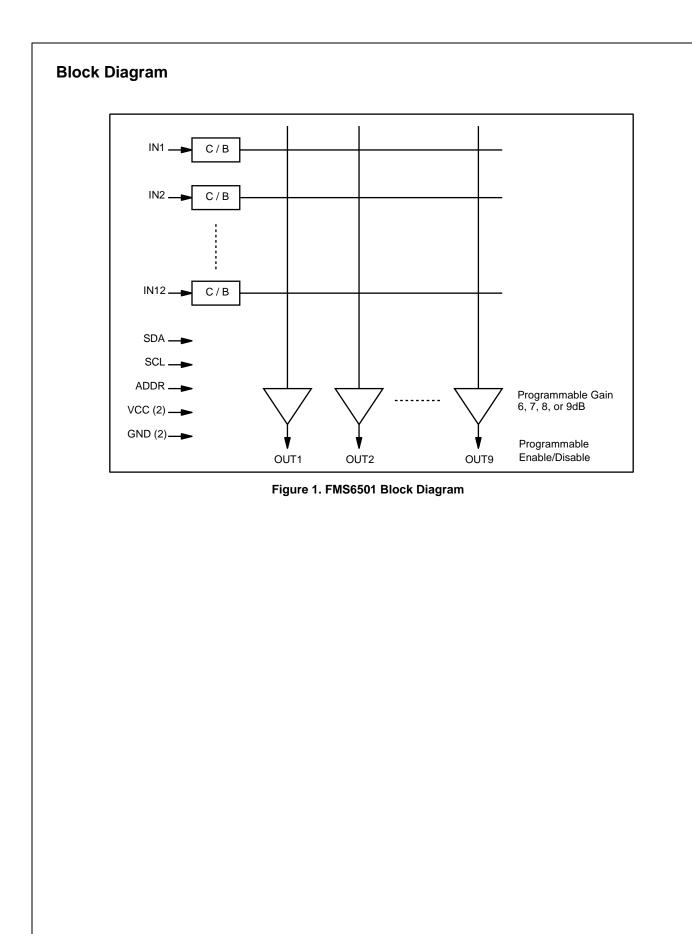

The FMS6501 switch matrix provides flexible options for today's video applications. The 12 inputs that can be routed to any of nine outputs. Each input can be routed to one or more outputs, but only one input may be routed to any one output. The input to output routing is controlled via an l^2C^{TM} -compatible digital interface.

Each input supports an integrated clamp option to set the output sync tip level of video with sync to ~300mV. Alternatively, the input may be internally biased to center signals without sync (Chroma, Pb, Pr) at ~1.25V. These DC output levels are for the 6dB gain setting. Higher gain settings increase the DC output levels accordingly. The input clamp / bias mode is selected via I^2C .

Unused outputs may be powered down to reduce power dissipation.

Absolute Maximum Ratings

Stresses exceeding the absolute maximum ratings may damage the device. The device may not function or be operable above the recommended operating conditions and stressing the parts to these levels is not recommended. In addition, extended exposure to stresses above the recommended operating conditions may affect device reliability. The absolute maximum ratings are stress ratings only.

Parameter	Min.	Max.	Unit

CDM	Charged Device Model	2	kV

Digital Interface

The l^2 C-compatible interface is used to program output enables, input to output routing, input clamp / bias, and output gain. The l^2 C address of the FMS6501 is 0x06 (0000 0110) with the ability to offset it to 0x86 (1000 0110) by tying the ADDR pin high.

Both data and address data, of eight bits each, are written to the I^2C address to access all the control functions.

There are separate internal addresses for each output. Each output's address includes bits to select an input channel, adjust the output gain, and enable or disable the output amplifier. More than one output can select the same input channel for one-to-many routing. When the outputs are disabled, they are placed in a high-impedance state. This allows multiple FMS6501 devices to be paralleled to create a larger switch matrix. Typical output power-up time is less than 500ns.

The clamp / bias control bits are written to their own internal address, since they should always remain the same regardless of signal routing. They are set based on the input signal connected to the FMS6501.

All undefined addresses may be written without effect.

Control Name	Width	Туре	Default	Bit(s)	Description
Enable	1 bit	Write	0	7	Channel Enable: 1=Enable, 0=Power Down ⁽¹⁾

Output Control Register Contents and Defaults

Notes:

1. Power down places the output in a high-impedance state so multiple FMS6501 devices may be paralleled. Power down also de-selects any input routed to the specified output.

2. When all inputs are OFF, the amplifier input is tied to approximately 150mV and the output goes to approximately 300mV with the 6dB gain setting.

Notes:

1. 100% tested at 25°C.

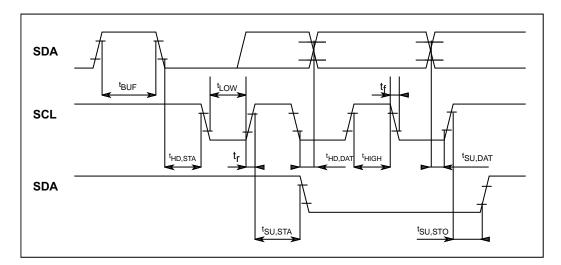

Figure 3. I²C Bus Timing

I²C Interface

Operation

The I^2C -compatible interface conforms to the I^2C specification for Standard Mode. Individual addresses may be written. There is no read capability. The interface consists of two lines. These is a serial data line (SDA) and a serial clock line (SCL), both of which must be connected to a positive supply through an external resistor. Data transfer may be initiated only when the bus is not busy.

Bit Transfer

One data bit is transferred during each clock pulse. The data on the SDA line must remain stable during the HIGH period of the clock pulse. Changes in the line during this time are interpreted as a control signal.

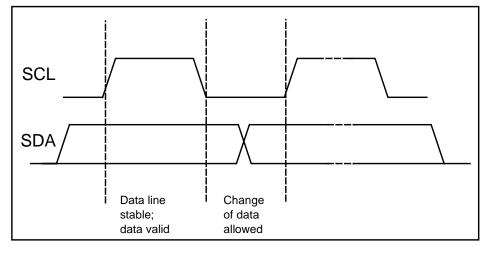

Figure 4. Bit Transfer

Start and Stop Conditions

The data and clock lines remain HIGH when the bus is not busy. A HIGH-to-LOW transition of the data line, while the clock is HIGH, is defined as START condition (S). A LOW-to-HIGH transition of the data line, while the clock is HIGH, is defined as STOP condition (P).

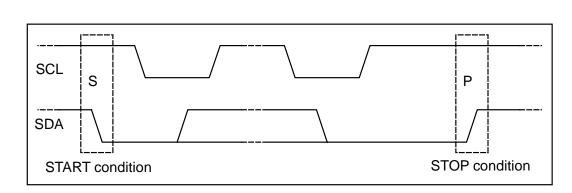

Figure 5. Definition of START and STOP conditions

Acknowledge

The data bytes transferred between the START and STOP conditions from transmitter to receiver is unlimited. Each byte of eight bits is followed by an acknowledge bit. The acknowledge bit is a high-level signal put on the bus by the transmitter, during which the master generates an extra acknowledge-related clock pulse. A slave receiver must generate an acknowledge after the reception of each byte. A master receiver must generate an acknowledge after the reception of each byte that has been clocked out of the slave transmitter. The device that acknowledges must pull down the SDA line during the acknowledge clock pulse so the SDA line is stable LOW during the HIGH period of the acknowledge-related clock pulse (set-up and hold times must be taken into consideration). A master receiver must signal an end of data to the transmitter by not generating an acknowledge on the last byte clocked out of the slave. In this event, the transmitter must leave the data line HIGH to enable the master to generate a STOP condition.

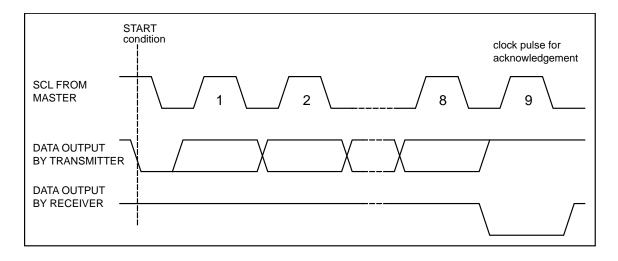

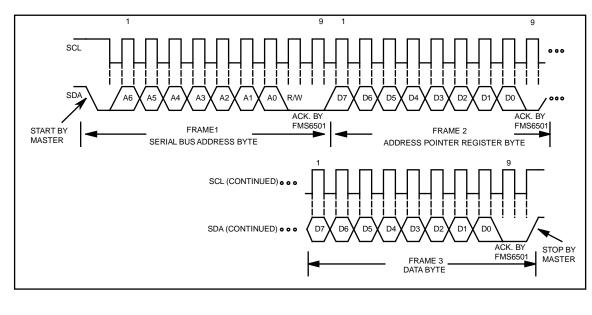

Figure 6. Acknowledgement on the I²C Bus

I²C Bus Protocol

Before any data is transmitted on the I^2C bus, the device that should respond is addressed first. The addressing is always carried out with the first byte transmitted after the start procedure. The I^2C bus configuration for a data write to the FMS6501 is shown in Figure 5.

Applications Information

Input Clamp / Bias Circuitry

The FMS6501 accommodates AC- or DC-coupled inputs.

Internal clamping and bias circuitry are provided to support AC-coupled inputs. These are selectable through the CLMP bits via the I^2C compatible interface.

For DC-coupled inputs, the device should be programmed to use the 'bias' input configuration. In this configuration, the input is internally biased to 625mV through a 100k Ω resistor. Distortion is optimized with the output levels set between 250mV above ground and 500mV below the power supply. These constraints, along with the desired channel gain, need to be considered when configuring the input signal levels for input DC coupling.

With AC-coupled inputs, the FMS6501 uses a simple clamp rather than a full DC-restore circuit. For video signals with and without sync (Y,CV,R,G,B), the lowest voltage at the output pins is clamped to approximately 300mV above ground when the 6dB gain setting is selected.

If symmetric AC-coupled input signals are used (chroma,Pb,Pr,Cb,Cr), the bias circuit described above can be used to center them within the input common range. The average DC value at the output is approximately 1.27V with a 6dB gain setting. This value changes depending upon the selected gain setting.

Gain Setting	Clamp Voltage	Bias Voltage
6dB	300mV	1.27V
7dB	330mV	1.43V
8dB	370mV	1.60V
9dB	420mV	1.80V

Figure 8 shows the clamp mode input circuit and the internally controlled voltage at the input pin for AC-coupled inputs.

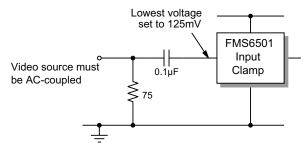

Figure 8. Clamp Mode Input Circuit

Figure 9 shows the bias mode input circuit and internally controlled voltage at the input pin for AC-coupled inputs.

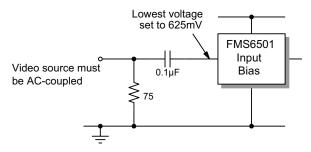

Figure 9. Bias Mode Input Circuit

Output Configuration

The FMS6501 outputs may be either AC or DC coupled. Resistive output loads can be as low as 75Ω , representing a dual, doubly terminated video load. High impedance, capacitive loads up to 20pF can also be driven without loss of signal integrity. For standard 75Ω video loads, a 75Ω matching resistor should be placed in series to allow for a doubly terminated load. DC-coupled outputs should be connected as shown in Figure 10.

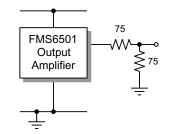

Figure 10. DC-Coupled Load Connection

If multiple low-impedance loads are DC coupled, increased power and thermal issues need to be addressed. In this case, the use of a multilayer board with a large ground plane to help dissipate heat is recommended. If a two-layer board is used under these conditions, an extended ground plane directly under the device is recommended. This plane should extend at least 0.5 inches beyond the device. PC board layout issues are covered in the Layout Considerations section.

AC-coupled loads should be configured as in Figure 11:

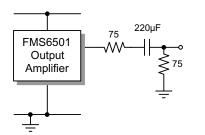

Figure 11. AC-Coupled Load Connection

Thermal issues are significantly reduced with AC-coupled outputs, alleviating special PC layout requirements.

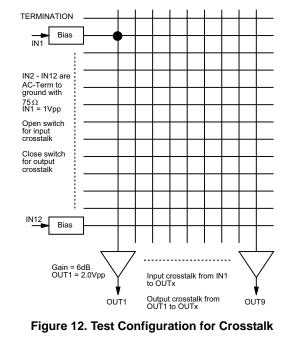

Each of the outputs can be independently powered down and placed in a high-impedance state with the ENABLE bit. This function can be used to mute video signals, to parallel multiple FMS6501 outputs, or to save power. When the output amplifier is disabled, the high-impedance output presents a $3k\Omega$ load to ground. The output amplifier typically enters and recovers from the powerdown state in less than 300ns after being programmed.

When an output channel is not connected to an input, the input to that channel's amplifier is forced to approximately 150mV. The output amplifier is still active unless specifically disabled by the I²C interface. Voltage output levels depend on the programmed gain for that channel.

Crosstalk

Crosstalk is an important consideration when using the FMS6501. Input and output crosstalk are defined to represent the two major coupling modes in a typical application. Input crosstalk is crosstalk in the input pins and switches when the interfering signal drives an open switch. It is dominated by inductive coupling in the package lead frame between adjacent leads. It decreases rapidly as the interfering signal moves farther away from the pin adjacent to the input signal selected. Output crosstalk is coupling from one driven output to another active output. It decreases with increasing load impedance, as it is caused mainly by ground and power coupling between output amplifiers. If a signal is driving an open switch, its crosstalk is mainly input crosstalk. If it is driving a load through an active output, its crosstalk is mainly output crosstalk.

Input and output crosstalk measurements are performed with the test configuration shown in Figure 12.

For input crosstalk, the switch is open. All inputs are in bias mode. Channel 1 input is driven with a $1V_{pp}$ signal, while all other inputs are AC terminated with 75 Ω . All outputs are enabled and crosstalk is measured from IN1 to any output.

For output crosstalk, the switch is closed. Crosstalk from OUT1 to any output is measured.

Crosstalk from multiple sources into a given channel was measured with the setup shown in Figure 6. Input IN1 is driven with a 1V_{pp} pulse source and is connected to outputs Out1 to Out8. Input In9 is driven with a secondary, asynchronous, gray-field video signal, and is connected to Out9. All other inputs are AC terminated with 75 Ω . Crosstalk effects on the gray field are measured and calculated with respect to a standard 1V_{pp} output measured at the load.

If not all inputs and outputs are needed, avoid using adjacent channels, where possible, to reduce crosstalk. Disable all unused channels to further reduce crosstalk and power dissipation.

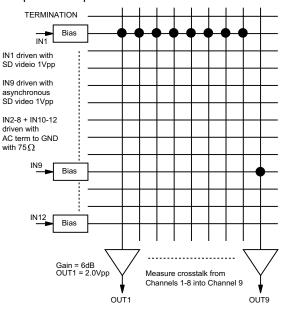

Figure 13. Test Configuration for Multi-Channel Crosstalk

Layout Considerations

General layout and supply bypassing play major roles in high-frequency performance and thermal characteristics. Fairchild offers a demonstration board, FMS6501DEMO, to use as a guide for layout and to aid in device testing and characterization. The FMS6501DEMO is a 4-layer board with a full power and ground plane. For optimum results, follow the steps below as a basis for high frequency layout.

- Include 10µF and 0.1µF bypass capacitors.
- Place the 10µF capacitor within 0.75 inches of the power pin.
- Place the 0.1µF capacitor within 0.1 inches of the power pin.
- Connect all external ground pins as tightly as possible, preferably with a large ground plane under the package.
- Layout channel connections to reduce mutual trace inductance.
- Minimize all trace lengths to reduce series inductances. If routing across a board, place device such that longer traces are at the inputs rather than the outputs.

If using multiple, low-impedance, DC-coupled outputs, special layout techniques may be employed to help dissipate heat.

If a multilayer board is used, a large ground plane directly under the device helps reduce package case temperature.

For dual-layer boards, an extended plane can be used.

Worst-case, additional die power due to DC loading can be estimated at ($V_{cc}^2/4R_{load}$) per output channel. This assumes a constant DC output voltage of $V_{cc}/2$. For 5V V_{cc} with a dual-DC video load, add 25/(4*75) = 83mW, per channel.

FMS6501 Video Switch Matrix Applications

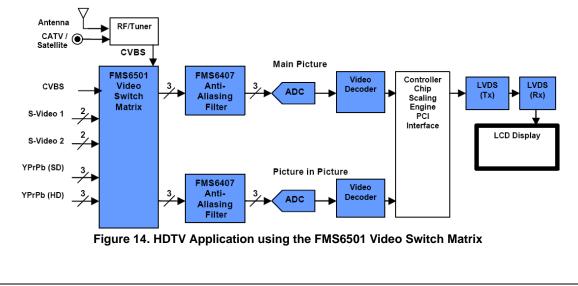

The increased demand for consumer multimedia systems has created a challenge for system designers to provide cost-effective solutions to capitalize on the growth potential in graphics display technologies. These applications requires cost-effective video switching and filtering solutions to deploy high-quality display technologies rapidly and effectively to the target audience. Areas of specific interest include HDTV, media centers, and automotive "infotainment" (includes navigation, in-cabin entertainment, and back-up camera). In all cases, the advantages an integrated video switch matrix provides are high quality video switching specific to the application, as well as video input clamps and on-chip, lowimpedance output cable drivers with switchable gain.

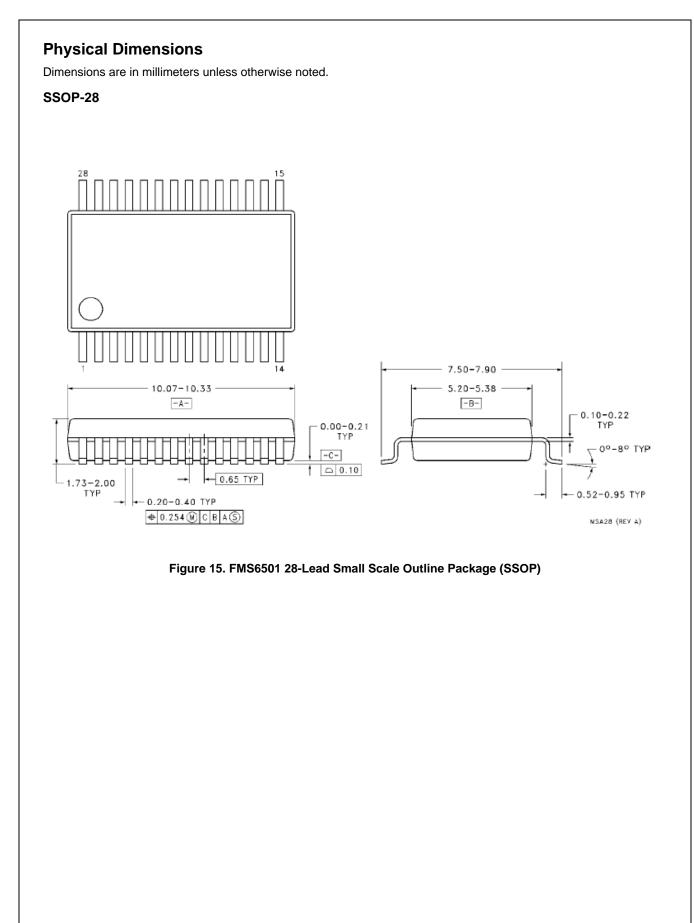

Generally the largest application for a video switch is for the front end of an HDTV, where it takes multiple inputs and routes them to appropriate signal paths (main picture and picture in picture - PiP). These are normally routed into ADCs followed by decoders. There are many different technologies for HDTV; including LCD, Plasma, and CRT, with similar analog switching circuitry.

An example of a HDTV application is shown in Figure 14. This system combines a video switch matrix and two three-channel switchable anti-aliasing filters. There are two three-channel signal paths in the system; one for the main picture, the other for "Picture in Picture" (PiP).

VIPDEMOTM Control Software

The FMS6501 is configured via an I²C-compatible digital interface. To facilitate demonstration, Fairchild Semiconductor had developed the VIPDEMOTM GUI-based control software to write to the FMS6501 register map. This software is included in the FMS6501DEMO kit. Also included is a parallel port I²C adapter and an interface cable to connect to the demo board. Besides using the full FMS6501 interface, the VIPDEMOTM can also be used to control single-register read and writes for I²C.
