DATASHEET

Low Input Voltage and High Efficiency Synchronous Boost Converter with 1.3A Switch

ISL9113

The ISL9113 provides a power supply solution for devices powered by three-cell alkaline, NiCd, NiMH or one-cell Li-Ion/Li-Polymer batteries. It offers either a fixed 5V or an adjustable output option for USB-OTG or portable HDMI applications. The device is guaranteed to supply 500mA from a 3V input and 5V output and has a typical 1.3A peak current limit. High 1.8MHz switching frequency allows for the use of tiny, low-profile inductors and ceramic capacitors to minimize the size of the overall solution.

The ISL9113 is an internally compensated, fully integrated synchronous converter optimized for efficiency with minimal external components. At light load, the device enters skip mode and consumes only 20µA of quiescent current, resulting in higher efficiency at light loads and maximum battery life.

The device is available in an 8 Ld DFN package and a 6 bump WLCSP.

Features

- · Up to 95% efficiency at typical operating conditions
- Input voltage range: 0.8V to 4.7V
- Output current: Up to 500mA (V_{BAT} = 3.0V, V_{OUT} = 5.0V)
- Low quiescent current: 20µA (typical)
- Logic control shutdown (I₀ < 1µA)
- Fixed 5V, 5.1V or adjustable output
- 1.2V EN high logic
- · Output disconnect during shutdown
- · Skip mode under light load condition
- Undervoltage lockout
- Fault protection: OVP (ADJ version only), OTP, short circuit
- 8 Ld 2mmx2mm DFN package and 6 bump 0.8mmx1.36mm WLCSP

Applications

- Products including portable HDMI and USB-OTG
- Smartphones

Detailed Description

Current Mode PWM Operation

The control scheme of the device is based on the peak current mode control and the control loop is compensated internally. The peak current of the N-channel MOSFET switch is sensed to limit the maximum current flowing through the switch and the inductor. The typical current limit is set to 1.3A.

The control circuit includes a ramp generator, slope compensator, error amplifier and a PWM comparator (see "Block Diagrams" on <u>pages 2</u> and <u>3</u>). The ramp signal is derived from the inductor current. This ramp signal is then compared to the error amplifier output to generate the PWM gating signals for driving both N-channel and P-channel MOSFETs. The PWM operation is initialized by the clock from the internal oscillator (typical <u>1.8MHz</u>). The N-channel MOSFET is turned ON at the beginning of a PWM cycle, the P-channel MOSFET remains OFF and the current starts ramping up. When the sum of the ramp and the slope compensator output reaches the error amplifier output voltage, the PWM comparator outputs a signal to turn OFF the N-channel MOSFET. Here, both MOSFETs remain OFF during the dead-time interval. Next, the P-channel MOSFET is turned ON and remains ON until the end of this PWM cycle. During this time, the inductor current ramps down until the next clock. At this point, following a short dead time, the N-channel MOSFET is again turned ON, repeating as previously described.

Skip Mode Operation

The boost converter is capable of operating in two different modes. When the inductor current is sensed to cross zero for eight consecutive times, the converter enters skip mode. In skip mode, each pulse cycle is still synchronized by the PWM clock. The N-channel MOSFET is turned ON at the rising edge of the clock and turned OFF when the inductor peak current reaches typically 25% of the current limit. Then, the P-channel MOSFET is turned ON, and it stays ON until its current goes to zero. Subsequently, both N-channel and P-channel MOSFETs are turned OFF until the next clock cycle starts, at which time the N-channel MOSFET is turned ON again. When V_{OUT} is 1.5% higher than the nominal output voltage, the N-channel MOSFET is immediately turned OFF and the P-channel MOSFET is turned ON until the inductor current goes to zero. The N-channel MOSFET resumes operation when V_{FB} falls back to its nominal value, repeating the previous operation. The converter returns to 1.8MHz PWM mode operation when V_{FB} drops 1.5% below its nominal voltage.

Given the skip mode algorithm incorporated in the ISL9113, the average value of the output voltage is approximately 0.75% higher than the nominal output voltage under PWM operation. This positive offset improves the load transient response when switching from skip mode to PWM mode operation. The ripple on the output voltage is typically $1.5\%*V_{OUT}$ (nominal) when input voltage is sufficiently lower than output voltage, and it increases as the input voltage approaches the output voltage.

Synchronous Rectifier

The ISL9113 integrates one N-channel MOSFET and one P-channel MOSFET to realize a synchronous boost converter. Because the commonly used discrete Schottky rectifier is replaced with the low $r_{DS(ON)}$ P-channel MOSFET, the power conversion efficiency reaches a value above 90%. Since a typical step-up converter has a conduction path from the input to the

output via the body diode of the P-channel MOSFET, a special circuit (see "Block Diagrams" on pages 2 and 3) is used to reverse the polarity of the P-channel body diode when the device is shut down. Thus, this configuration completely disconnects the load from the input during shutdown of the converter. The benefit of this feature is that the battery will not be completely depleted during shutdown of the converter. No additional components are needed to disconnect the battery from the output of the converter.

Soft-Start

The soft start-up duration is the time between the device being enabled and V_{OUT} rising to within 3% of target voltage. When the device is enabled, the start-up cycle starts with a linear phase. During the linear phase, the rectifying switch is turned ON in a current limited configuration, delivering about 350mA, until the output capacitor is charged to approximately 90% of the input voltage. At this point, PWM operation begins in boost mode. If the output voltage is below 2.3V, PWM switching is done at a fixed duty-cycle of 75% until the output voltage reaches 2.3V. When the output voltage exceeds 2.3V, the closed-loop current mode PWM loop overrides the duty cycle until the output voltage is regulated. Peak inductor current is ramped to the final value (typically 1.3A) during the soft-start period to limit inrush current from the input source. Fault monitoring begins approximately 2ms after the device is enabled.

Over-temperature Protection (OTP)

The device offers over-temperature protection. A temperature sensor circuit is integrated and monitors the internal IC temperature. Once the temperature exceeds the preset threshold (typically +150°C), the IC shuts down immediately. The OTP has a typical hysteresis of +25°C. When the device temperature decreases by this, the device starts operating.

Fault Monitoring and Reporting

Fault monitoring starts 2ms after start-up. Table 1 shows the response to different detected faults. Any fault condition shown in Table 1 causes the FAULT pin to be taken LOW. The FAULT pin will not release until V_{BAT} and V_{OUT} fully collapse or until the fault condition is removed.

Printed Circuit Board Layout Recommendations

The ISL9113 is a high frequency switching boost converter. Accordingly, the converter has fast voltage change and high switching current that may cause EMI and stability issues if the layout is not done properly. Therefore, careful layout is critical to minimize the trace inductance and reduce the area of the power loop.

Power components, such as input capacitor, inductor and output capacitor, should be placed close to the device. Board traces that carry high switching current should be routed wide and short. A solid power ground plane is important for EMI suppression.

The switching node (SW pin) of the converter and the traces connected to this pin are very noisy. Noise sensitive traces, such as the FB trace, should be kept away from SW node. The voltage divider should be placed close to the FB pin to prevent noise pickup. Figures 4 and 5 show the recommended PCB layout.

In the 8 Ld DFN package, the heat generated in the device is mainly dissipated through the thermal pad. Maximizing the copper area connected to the thermal pad is preferable. It is recommended to add at least 4 vias within the pad to the GND plane for the best thermal relief.

FIGURE 5. RECOMMENDED PCB LAYOUT (WLCSP VERSION)

Fixed and Adjustable Output Voltage

ISL9113 offers options for fixed output voltage of 5V, 5.1V or an adjustable output voltage.

For the fixed output voltage version (ISL9113ER7Z, ISL9113EI9Z-T), an internal voltage divider is used (see "Block Diagrams", <u>"ISL9113ER7Z" on page 2</u>). For the adjustable output voltage version (ISL9113ERAZ), the output voltage is programmed by connecting two external voltage divider resistors between V_{OUT}, FB and GND (see "Block Diagrams", <u>"ISL9113ERAZ" on page 3</u>).

TABLE 1. FAULT DETECTION AND RESPONSE

FAULT CONDITION	DETECTION DETAILS	ACTION	
Low Battery Voltage	V _{BAT} < 0.7V	Shut down until V_{EN} or V_{BAT} is cycled.	
V _{OUT} out of Regulation	V_{OUT} is 10% below the target output voltage	Shut down only if V _{BAT} and V _{OUT} fall below 2.1V. Device automatically restarts after 200ms. FAULT signal switches ON and OFF when V _{OUT} drops out of regulation due to overload condition.	
Short Circuit	V _{OUT} falls below V _{BAT}	Shut down immediately. Device automatically restarts after 200ms.	
Over-temperature Protection	Die temperature is > +150°C	Switching stops. Device automatically restarts when temperature decreases to +125°C.	
Output Overvoltage Protection (ADJ version only)	V _{OUT} > 5.9V	Switching stops until EN pin is toggled or power is cycled.	

Output Voltage Setting Resistor Selection

For the ISL9113 adjustable output version, resistors R₁ and R₂, shown in the Block Diagram <u>"ISL9113ERAZ" on page 3</u>, set the desired output voltage values. The output voltage can be calculated using <u>Equation 1</u>:

$$V_{OUT} = V_{FB} \bullet \left(1 + \frac{R_1}{R_2} \right)$$
 (EQ. 1)

where V_{FB} is the internal FB reference voltage (0.8V typical). The current flowing through the divider resistors is calculated as $V_{OUT}/(R_1+R_2)$. Large resistance is recommended to minimize current into the divider and thus improve the total efficiency of the converter. R_1 and R_2 should be placed close to the FB pin of the device to prevent noise pickup.

Inductor Selection

An inductor with core material suitable for high frequency applications (e.g., ferrite) is desirable to minimize core loss and improve efficiency. The inductor should have a low ESR to reduce copper loss. Moreover, the inductor saturation current should be higher than the maximum peak current of the device; i.e., **1.5A**.

The device is designed to operate with an inductor value of 2.2µH to provide stable operation across the range of load, input and output voltages. Stable mode switching between PWM and skip mode operation is guaranteed at this inductor value. <u>Table 2</u> shows recommended inductors.

Capacitor Selection

INPUT CAPACITOR

A minimum of a 4.7 μ F ceramic capacitor is recommended to provide stable operation under typical operating conditions. For input voltage less than 1.0V application, an additional 4.7 μ F ceramic capacitor is recommended for better noise filtering and EMI suppression. The input capacitor should be placed close to the input pin, GND pin and the non-switching terminal of the inductor.

OUTPUT CAPACITOR

For the output capacitor, a ceramic capacitor with small ESR is recommended to minimize output voltage ripple. A typical 4.7μ F should be used to provide stable operation at different typical operating conditions. The output capacitor should be placed close to the output pin and GND pin of the device. <u>Table 3</u> shows the recommended capacitors.

About Intersil

Intersil Corporation is a leading provider of innovative power management and precision analog solutions. The company's products address some of the largest markets within the industrial and infrastructure, mobile computing and high-end consumer markets.

For the most updated datasheet, application notes, related documentation and related parts, please see the respective product information page found at <u>www.intersil.com</u>.

You may report errors or suggestions for improving this datasheet by visiting www.intersil.com/ask.

Reliability reports are also available from our website at www.intersil.com/support

For additional products, see www.intersil.com/en/products.html

Intersil products are manufactured, assembled and tested utilizing ISO9001 quality systems as noted in the quality certifications found at www.intersil.com/en/support/gualandreliability.html

Intersil products are sold by description only. Intersil Corporation reserves the right to make changes in circuit design, software and/or specifications at any time without notice. Accordingly, the reader is cautioned to verify that data sheets are current before placing orders. Information furnished by Intersil is believed to be accurate and reliable. However, no responsibility is assumed by Intersil or its subsidiaries for its use; nor for any infringements of patents or other rights of third parties which may result from its use. NOTES:

- 1. Dimensions and tolerance per ASME Y 14.5M 1994.
- 2 Dimension is measured at the maximum bump diameter parallel to primary datum Z.
- $\underline{3}$ Primary datum Z and seating plane are defined by the spherical crowns of the bump.
- 4. Bump position designation per JESD 95-1, SPP-010.
- 5. All dimensions are in millimeters.
- <u>6.</u> NSMD refers to non-solder mask defined pad design per Intersil Tech Brief <u>www.intersil.com/data/tb/tb451.pdf</u>
- 7. Ball height and post saw device size can vary by $\pm 10 \mu m$ depending on final selection of assembly vendor.
